

## METHOD FOR ADJUSTING THE TEMPERATURE OF A MOTOR VEHICLE SEAT

FIELD OF THE INVENTION

The present invention relates to a method for adjusting the temperature of a motor vehicle seat.

5 BACKGROUND INFORMATION

An aspect of designing a vehicle interior is to provide the occupant of a motor vehicle with optimum seating comfort. Special attention is directed here to the thermo-physiological comfort by regulating the transportation of heat and moisture.

10 No other component of the motor vehicle is in contact over such a large surface area and consistently with the occupant as the motor vehicle seat. Accordingly, a healthy and comfortable micro-climate is important between the seat surface and the occupant, this micro-climate having a positive  
15 effect on the mental and physical fitness of the occupant.

German Published Patent Application No. 198 51 979 describes a vehicle seat, in which, in order to set a comfortable seat climate, a control unit is provided which is connected on the  
20 input side to a temperature sensor for recording the temperature of the seat surface, the "integral sensor", and a moisture sensor, and is also connected on the output side to electric switching circuits of a seat heater and seat ventilating system. The control unit is additionally  
25 connected on the input side by an outside temperature sensor for measuring the ambient temperature. A temperature adjusting system is integrated in the control unit and adjusts the surface temperature of seat cushion and backrest cushion to a predetermined desired value by the seat heater and seat  
30 ventilating system. In this case, the desired value is corrected in the control unit as a function of the temperature value supplied by the outside sensor. The correction here can

take place in such a manner that, at an outside temperature of below 20°C, the desired value is set to, for example, 36°C, and at an outside temperature of above 20°C, the desired value is lowered to, for example, 35°C. With this arrangement for  
5 influencing the temperature which is to be adjusted at the seat surface, the seat user's perception of temperature depending on the time of year is taken into account.

#### SUMMARY

10 In an example embodiment of the present invention, a method is for adjusting the temperature of a motor vehicle seat, which includes a seat ventilating system and a seat heater, to a predetermined desired value  $T_{des}$ , in which the temperature  $T_s$  of the motor vehicle seat is detected in the region of the  
15 seat surface by a first temperature sensor and the outside temperature  $T_a$  is detected by a second temperature sensor, which may ensure, for an occupant, a permanently comfortable, warm and dry micro-climate between him and the seat surface.

20 According to an example embodiment of the present invention, in order to adjust the temperature  $T_s$  of a seat, a seat ventilating system is switched off below a first temperature threshold  $T_{a1}$  for the outside temperature  $T_a$ , and a seat heater is switched off above a second temperature threshold  
25  $T_{a2}$  for the outside temperature  $T_a$ . At low outside temperatures  $T_a$  (below the first temperature threshold  $T_{a1}$  the adjusting system operates in "winter mode"), the temperature  $T_s$  of the seat is therefore set only by the seat heater and without the seat ventilating system whereas, at high outside  
30 temperatures  $T_a$  (above the second temperature threshold  $T_{a2}$  the adjusting system operates in "summer mode"), the temperature  $T_s$  of the seat is set only by the seat ventilating system and without the seat heater. In the temperature interval for the outside temperature  $T_a$  between the two  
35 temperature thresholds  $T_{a1}$  and  $T_{a2}$ , both the seat heater and

the seat ventilating system may generally be used to adjust the temperature  $T_s$  of the seat. At low outside temperatures  $T_a$  when seat ventilating system and seat heater are activated in parallel by an occupant, a cool air draft may be felt at least in the upper body region. A large portion of the air fed into the motor vehicle seat by the seat ventilating system disappears from the backrest of the motor vehicle seat via the shoulder region of the occupant. The dry air supplied absorbs some of the moisture from the occupant's skin surface, resulting in an unpleasantly cool sensation for the occupant. A sensation which is perceived by the occupant as being entirely positive during summer weather conditions may be problematic at lower outside temperatures  $T_a$ . If the supply of air is constricted, the cool sensation may be perceived as being no longer so negative. During winter mode without use of the seat ventilating system, the occupant may no longer have the unpleasantly cool sensation, and the occupant may obtain an unlimited pleasant sensation. At higher outside temperatures  $T_a$ , with the seat heater and seat ventilating system operating together to adjust the temperature  $T_s$  of the seat, sweating which may be perceived as being unpleasant by the occupant starts. The best well-being for the occupant may be obtained if the seat heater is not used in the summer mode. With the present method, comfortable cushion temperatures which are in the region of the normal skin temperatures may be achieved in winter and in summer. The clothing and the skin of the occupant remain dry even under extreme climate conditions. A permanently comfortable, warm and dry micro-climate may be achieved between the seat surface and the occupant.

According to an example embodiment, the value for the first temperature threshold  $T_{a1}$  is set to be equal to the value for the second temperature threshold  $T_{a2}$ . For example, this common value is approx.  $18^{\circ}\text{C}$ . This may make it possible to

completely omit a transition region permitting a parallel use of seat heater and seat ventilating system, as a result of which the adjustment of the temperature  $T_s$  of the seat may be considerably simplified. In order to set the temperature  $T_s$  of the seat, use may be made, depending on the outside temperature  $T_a$ , in other words in summer or in winter mode, of only the seat ventilating system or the seat heater.

Example embodiments of the present invention are explained in more detail below with reference to the appended Figure.

#### BRIEF DESCRIPTION OF THE DRAWING

The Figure is a schematic block circuit diagram for adjusting a temperature  $T_s$  of a motor vehicle seat having a seat ventilation system and a seat heater.

#### DETAILED DESCRIPTION

As illustrated in the Figure, in a method for adjusting the temperature  $T_s$  of a motor vehicle seat to a predetermined desired value  $T_{des}$  which may be set via a control device, the temperature  $T_s$  of the seat is detected in the region of a seat surface by a first temperature sensor 2 and is compared with the desired value  $T_{des}$ . In addition, the outside temperature  $T_a$  is measured with a second temperature sensor 4 and is compared with a threshold value  $T_{ax}$  for the outside temperature  $T_a$ .

The deviation  $T_{des}-T_s$  between the predetermined desired value  $T_{des}$  and the temperature  $T_s$  of the seat is processed by a first controller 6 for a seat heater 8 or by a second controller 10 for a seat ventilating system 12. Either the seat heater 8 is set in accordance with an output variable of the first controller 6 or the seat ventilating system 12 is set in accordance with an output variable of the second

controller 10 as a function of the switching position of a switch 14 with a temperature-dependent switching function.

The temperature-dependent switching function of the switch 14 is configured such that, below a predetermined threshold value  $T_{ax}$  for the outside temperature  $T_a$ , a "winter mode", only the seat heater 8 is set with the adjusting system via the first controller 6. The seat ventilating system 12 is switched off in winter mode. Above the predetermined threshold value  $T_{ax}$  for the outside temperature  $T_a$ , a "summer mode", only the seat ventilating system 12 is set with the adjusting system via the second controller 10. The seat heater 8 is switched off in summer mode. A temperature value of approximately 18°C may correspond to the threshold value  $T_{ax}$ . A delimitation between winter and summer mode at this threshold value  $T_{ax}$  for the outside temperature  $T_a$  may be perceived as being particularly pleasant by occupants. The threshold value  $T_{ax}$  may be varied as a function of individual perception. Furthermore, by deactivating the adjusting system, a manual actuation of seat heater 8 and seat ventilating system 12 may be ensured.

In an exemplary embodiment, the threshold value  $T_{ax}$  for the outside temperature  $T_a$  is divided into a first temperature threshold  $T_{a1}$  and a second temperature threshold  $T_{a2}$  with  $T_{a1}$  smaller than  $T_{a2}$ . The seat ventilating system 12 is switched off below the first temperature threshold  $T_{a1}$ , and the seat heater 8 is switched off above the second temperature threshold  $T_{a2}$ . The winter and summer mode is separated by the temperature interval between the two temperature thresholds  $T_{a1}$  and  $T_{a2}$  in which a mixed mode is possible. In the temperature interval, seat heater 8 and seat ventilating system 12 may be used in parallel for adjusting the temperature  $T_s$  of the seat in order to improve the seating comfort for the occupants. However, an individual operation of seat heater 8 and seat ventilating system 12 is also

possible in this temperature interval bounded by the temperature thresholds  $Ta1$  and  $Ta2$ .

In the exemplary embodiment illustrated in the Figure, the value for the first temperature threshold  $Ta1$  is therefore selected to be equal to the value for the second temperature threshold  $Ta2$  as a special case.

The predetermined desired value  $Tdes$  for the temperature  $Ts$  of the seat has a value in the temperature range between  $32.5^{\circ}\text{C}$  and  $35.5^{\circ}\text{C}$  which may correspond to the individual well-being of the occupant and may be set individually. Irrespective of the outside temperature  $Ta$ , occupants may prefer a narrow temperature range for the temperature  $Ts$  of the seat, which they perceive as being pleasant. This may be in the given temperature range of between  $32.5^{\circ}\text{C}$  and  $35.5^{\circ}\text{C}$  and may be independent of summer and winter mode.

In an example embodiment of the method, the temperature  $Ts$  of the seat may be adjusted to an upper desired value  $Tdesu$  below the first temperature threshold  $Ta1$  for the outside temperature  $Ta$ , and the temperature  $Ts$  of the seat may be adjusted to a lower desired value  $Tdesl$  above the second temperature threshold  $Ta2$  for the outside temperature  $Ta$ , the lower desired value  $Tdesl$  being smaller than the upper desired value  $Tdesu$ . Both desired values  $Tdesl$  and  $Tdesu$  may be in the temperature range between  $32.5^{\circ}\text{C}$  and  $35.5^{\circ}\text{C}$ . Account is therefore taken of the personal finding that in summer mode a somewhat cooler temperature  $Ts$  of the seat may be preferred than in winter, as a result of which a freshening effect may be obtained.

With the indicated method, the occupant may be provided with a comfortable micro-climate in the seat region which to the greatest possible extent may prevent unpleasant sensations in

terms of feelings with regard to the thermo-physiological seating comfort.

# ABSTRACT

In a method for adjusting the temperature of a motor vehicle seat, which includes a seat ventilating system and a seat heater, to a predetermined desired value, in which the  
5 temperature of the seat is detected in the region of a seat surface by a first temperature sensor and the outside temperature is detected by a second temperature sensor, the seat ventilating system is switched off below a first temperature threshold for the outside temperature, and the  
10 seat heater is switched off above a second temperature threshold for the outside temperature. By these measures, an occupant may be provided with a comfortable micro-climate in the seat region for his/her well-being.
